

## Exception Handling and Pickling

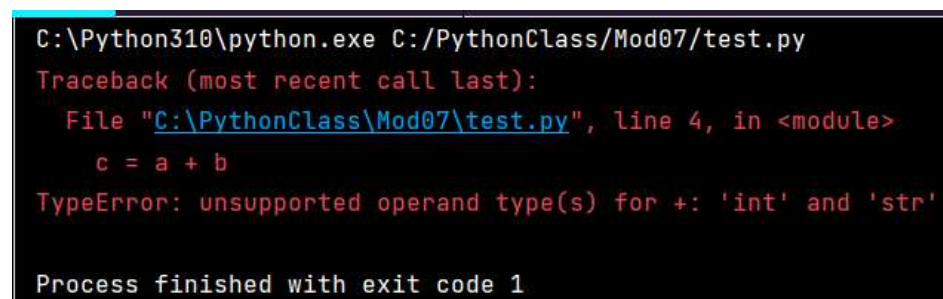

### Introduction

In this report, I will give an overview of Exception Handling and Pickling in Python. I will go over a Python script I created to demonstrate these two concepts. The program presents the user with two separate demos, one for each concept that the user can choose to view.

### Exception Handling

In Python, errors that occur during code execution are called exceptions. When exceptions occur, Python stops the program and displays an error message detailing the exception (Figure 1). There are a number of exception types. A few common ones are:

- `TypeError` - occurs when an operation is applied to objects of inappropriate types.
- `ValueError` - occurs when an operation receives an argument that has the right type but an inappropriate value.
- `ZeroDivisionError` – occurs when the second argument of a division operation is zero.

A screenshot of a terminal window with a black background and white text. The text shows a command to run a Python script, followed by a traceback indicating a TypeError. The error message states that an unsupported operand type(s) for addition were provided: an integer and a string. The process finished with an exit code of 1.

```
C:\Python310\python.exe C:/PythonClass/Mod07/test.py
Traceback (most recent call last):
  File "C:\PythonClass\Mod07\test.py", line 4, in <module>
    c = a + b
TypeError: unsupported operand type(s) for +: 'int' and 'str'

Process finished with exit code 1
```

Figure 1: Example of a Python error message when a `TypeError` exception occurs.

Exception handling is used to catch and handle the errors so that the program does not end abruptly and allows the program to continue running. This is accomplished with the `try` and `except` block. Python executes code following the `try` statement and if any exceptions occur while running this code, instead of stopping the program, Python executes the code following the `except` statement as a response to the exceptions in the preceding `try` clause. (Figure 2)

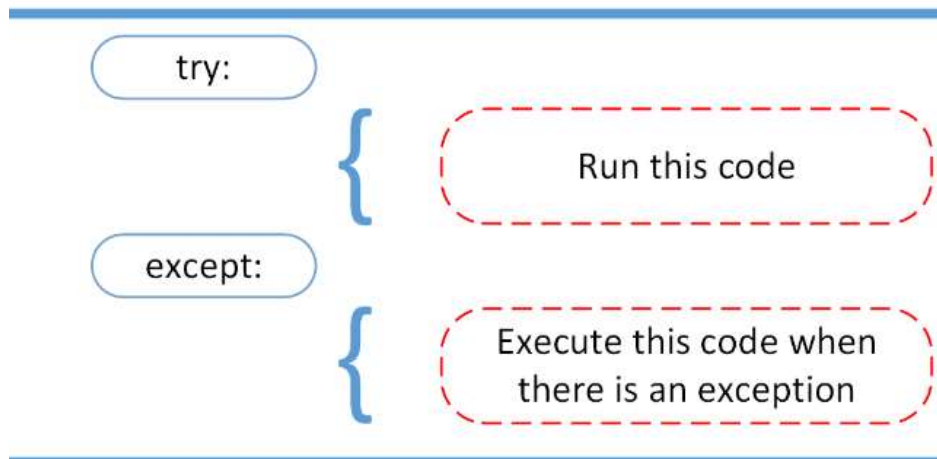

Figure 2: Try...Except block for exception handling. Image from RealPython.com

In my demo script, I use a simple math operation to demonstrate exception handling with try and except blocks. In the try clause, I use the operation to dividing the value of 100 by another value to generate exceptions. Then use the except clause to inform the user that an exception has occur and provide feedback on what that exception was before moving on and continue running the rest of the script. The demo runs through creating a couple of different exceptions that can occur while performing the division operation on purpose and catches them. In my try and except block, I have a few except clause to catch a few of the more common exceptions like dividing by zero or trying to divide different data types and a general catch all one to handle all other type of exceptions. (Figure 3)

```
36 | try:
37 |     quotient = round(float(num1) / float(num2), 2)
38 |     msg = str(num1) + " divide by " + str(num2) + " is: " + str(quotient) + " - No Errors -- Division successful."
39 |     return quotient, msg
40 |
41 | except ZeroDivisionError as e: # handles divide by zero
42 |     message = str(num1) + " divide by " + str(num2) + " is: Error -- Cannot divide by 0."
43 |     return e, message
44 |
45 | except ValueError as e: # handles non numeric values
46 |     message = str(num1) + " divide by " + str(num2) + " is: Error -- Use numbers only. Cannot mix strings and numbers."
47 |     return e, message
48 |
49 | except Exception as e: # handles all other error types and provides details
50 |     message = "Error -- Something is wrong"
51 |     return e, message
```

Figure 3: Try...Except blocks to handle exceptions that may occur during division operation.

## Pickling/Unpickling

Pickling is the process of converting complex data or objects in Python into binary format for storage in a binary file. The binary format can obscure the file's content in a non-human readable format. The pickle module must first be imported into the script for the pickle function to be available for use. Pickling data to a file is very similar to writing standard data to a text file. Open a binary (".dat") file and then call the pickle function and the *dump()* method, passing in the data to be pickled and the file as arguments, to convert the data into binary format and write to the file. (Figure 4)

```

102     pickle_obj = open(file_name, "wb")
103     pickle.dump(data_lst, pickle_obj)
104     pickle_obj.close()

```

Figure 4: Sample code of pickling data to binary file.

Unpickling is just the reversal of the pickling process. It reads in a binary file and converts the binary formatted data and converts it back to its original human readable format. This is accomplished with the *load()* method and it's again similar to reading in standard data from a text file. (Figure 5)

```

65     pickle_obj = open(file_name, "rb")
66     data_lst = pickle.load(pickle_obj)
67     pickle_obj.close()

```

Figure 5: Sample code of unpickling data from a binary file.

In my demo script, I demonstrate reading in and unpickling a table of data (list of dictionary rows) from a binary file. Print out the table for the user to see. After that, ask the user to input new data to be added to the list. Then pickle that list back to the binary file.

## Running the script

I ran the script in both PyCharm and the command window and it ran properly on both. Here is the program running in the command window. (Figure 6)

```

Command Prompt - py C:\PythonClass\Assignment07\test9.py
Microsoft Windows [Version 10.0.19042.1826]
(c) Microsoft Corporation. All rights reserved.

C:\Users\hho>py C:\PythonClass\Assignment07\test9.py

Welcome to the Exception Handling and Pickling Demo

Menu of Options
1) Exception Handling Demo
2) Pickling Demo
3) Exit Program

Which option would you like to perform? [1 to 3] - 1

----- This is the Exception (Error) handling demo -----

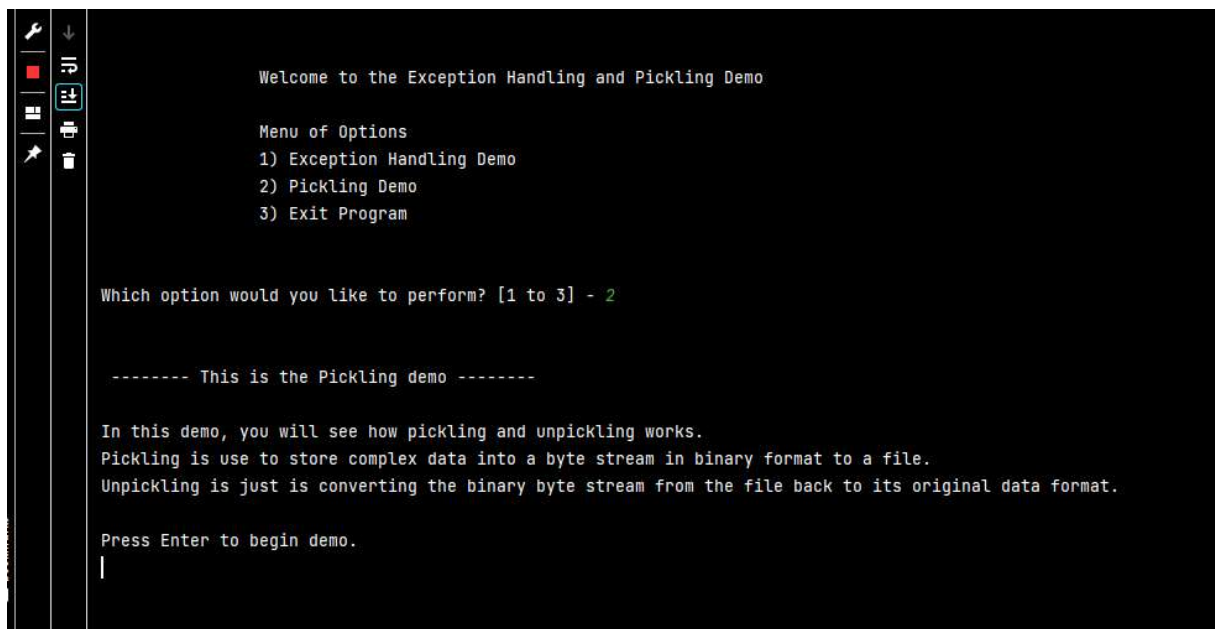

In this demo you will see how Python handles some execution errors.
A simple math operation is used to demonstrate this.

Press Enter to begin the demo.

```

Figure 6: Program running in command window.

This is the script running in PyCharm. (Figure 7)

```
Welcome to the Exception Handling and Pickling Demo

Menu of Options
1) Exception Handling Demo
2) Pickling Demo
3) Exit Program

Which option would you like to perform? [1 to 3] - 2

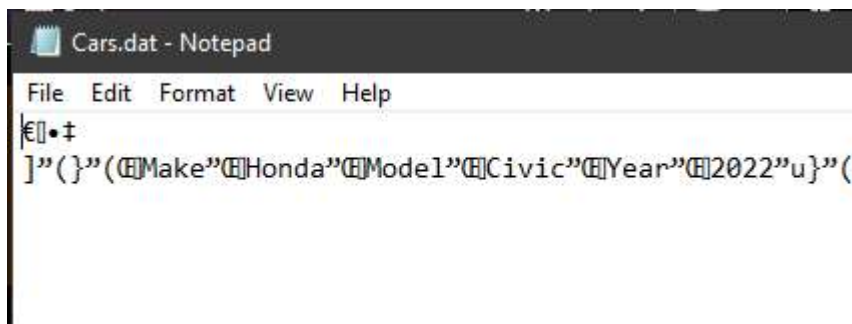

----- This is the Pickling demo -----

In this demo, you will see how pickling and unpickling works.
Pickling is use to store complex data into a byte stream in binary format to a file.
Unpickling is just is converting the binary byte stream from the file back to its original data format.

Press Enter to begin demo.

```

Figure 7: Program running in PyCharm.

This is a screenshot of the text file to verify that data is successfully written to a text file. (Figure 8)

```
Cars.dat - Notepad
File Edit Format View Help
[Garbled text: ]"({}"(E Make"H Honda"EModel"C Civic"E Year"E 2022"u}]"(
```

Figure 8: Verifying the data is in the binary file.

## Summary

I gave an overview of two concepts in Python. One is exception handling with the use of the try and except block. The other is pickling and the use of the dump() and load() methods to write and read to binary files. I wrote a script that runs through a demonstration of each.
